Service Manager is a comprehensive, integrated service management platform and service desk software solution. It automates IT and non-IT workflows and tasks to increase user satisfaction, decrease ticket volumes, and resolve issues and service requests faster.

Service Manager 9.5*x* or later is available in two modes: Hybrid and Codeless. The main difference between the two modes is the extent to which Process Designer technology is implemented.

- Service Manager **Codeless** fully implements Process Designer workflows and functionality in the Service Desk, Incident Management, Problem Management, Change Management, Request Fulfillment, Knowledge Management, Service Level Management, and Service Catalog modules.
- Service Manager **Hybrid** eases the transition between Service Manager Classic and Service Manager Codeless. In Hybrid mode, Process Designer technology is fully implemented, however you can continue to use legacy technology such as Format Control. This enables you to continue to use tailoring that you implemented using legacy technology until the time that you choose to migrate Service Manager to Codeless mode.

You can deploy Service Manager on-premises or in the cloud (AWS or Azure). For more information, see Install.

Service Manager utilizes a per-user schema for licensing and has two types of user licenses: login licenses (named or floating, which only control initial logins), and application licenses (which control access to individual modules).

- Named user licenses are assigned to specific users of Service Manager and guarantee access to the system. This license type is primarily used for dedicated users requiring guaranteed and immediate access. Examples of this type of user would be Service Manager administrators, process super users, and process engineers.
- Floating user licenses provide a pool of access to a set of users. Floating user licenses are primarily used for general users and provide first-come-first-serve access. Once the number of users accessing the system reaches the number of floating licenses purchased, each additional user trying to access Service Manager will be notified that the maximum number of users has been reached and be denied access.

- Application licenses control the users' access to individual Service Manager modules. Logging in as any user with update capacity for a business module consumes a license for that module. Update capacity includes permission to add, update, or delete any record associated with the module.

For more information, see License tracking.
